- Enhances artificial intelligence by understanding human cognition.
- Provides insights into the evolution of the human brain and cognition.

Relevance to Psych 3BN3

In the context of Psych 3BN3, students and researchers delve deeply into the neural underpinnings

of cognitive functions, exploring how specific brain regions contribute to processes like memory encoding, language comprehension, or decision-making. The course often emphasizes both theoretical models and empirical evidence, fostering a nuanced understanding of brain-behavior relationships.

Core Concepts in Cognitive Neuroscience

Neural Substrates of Cognition

Key brain regions implicated in cognitive functions include:

- Prefrontal Cortex (PFC): Central to executive functions such as planning, decision-making, and working memory.
- Hippocampus: Essential for the formation and retrieval of declarative memories.
- Temporal Lobes: Involved in auditory processing and language comprehension.
- Parietal Lobes: Play roles in spatial awareness and attention.
- Occipital Lobes: Primary centers for visual processing.

Understanding how these areas interact allows researchers to map cognitive functions to specific neural circuits.

Neural Networks and Connectivity

Cognition emerges from the dynamic interplay of distributed neural networks rather than isolated regions. Notable networks include:

- Default Mode Network (DMN): Active during rest and self-referential thought.
- Central Executive Network (CEN): Engaged during tasks requiring attention and problem-solving.
- Salience Network: Detects and filters salient stimuli, mediating switching between DMN and CEN.

These networks are interconnected via white matter tracts, facilitating rapid communication essential for complex cognition.

Neuroplasticity and Cognitive Adaptability

Neuroplasticity refers to the brain's ability to reorganize and form new connections in response to experience, learning, or injury. This adaptability underpins cognitive development and recovery,

making it a central theme in cognitive neuroscience research and clinical applications.

Methodologies in Psych 3BN3 Cognitive Neuroscience

Neuroimaging Techniques

Advancements in neuroimaging have revolutionized our understanding of brain function:

- Functional Magnetic Resonance Imaging (fMRI): Measures blood-oxygen-level-dependent (BOLD) signals, indicating neural activity. It allows for the mapping of active brain regions during specific tasks.
- Electroencephalography (EEG): Records electrical activity with high temporal resolution, suitable for studying rapid cognitive processes like attention shifts or language processing.
- Magnetoencephalography (MEG): Detects magnetic fields produced by neural currents, combining spatial and temporal precision.
- Positron Emission Tomography (PET): Uses radioactive tracers to measure metabolic activity and neurotransmitter systems.

Behavioral and Experimental Paradigms

Psych 3BN3 incorporates various experimental tasks to probe cognitive functions, such as:

- Working Memory Tasks: N-back or digit span tests assess the capacity and neural correlates of working memory.
- Language Tasks: Semantic and syntactic processing experiments reveal language network dynamics.
- Decision-Making Tasks: Risk assessment and reward-based paradigms illuminate executive function and reward circuitry.
- Attention Tasks: Stroop or Posner cueing tasks evaluate attentional control mechanisms.

Neurostimulation and Manipulation Methods

Techniques like Transcranial Magnetic Stimulation (TMS) and Transcranial Direct Current Stimulation (tDCS) allow researchers to transiently modulate neural activity, establishing causal links between brain regions and cognitive functions.
