Common Electrochemistry Lab Report Questions and Answers

Understanding typical questions asked in electrochemistry lab reports helps students prepare accurate answers. Here are some common questions along with detailed explanations:

1. What is the purpose of the electrochemical cell used in the experiment?

Answer:

The primary purpose of the electrochemical cell in the experiment is to facilitate the transfer of electrons between electrodes through an electrolyte solution. This setup allows the measurement of electrical potentials, current flow, and reaction tendencies of different chemical species. It helps in understanding oxidation-reduction (redox) reactions, determining electrode potentials, and studying electrochemical behaviors under controlled conditions.

2. How do you calculate the standard electrode potential from the experimental data?

Answer:

To calculate the standard electrode potential (E°), follow these steps:

- Record the measured cell potential (E_{cell}) under standard conditions.
- Use the Nernst equation to relate the measured potential to the standard potential, considering the concentrations of reactants and products.
- For a cell involving half-reactions, apply the equation:

\[

$$E^\circ_{\text{cell}} = E^\circ_{\text{cathode}} - E^\circ_{\text{anode}}$$

\]

- If the cell is not standard, adjust for concentration differences using the Nernst equation:

\[

$$E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{RT}{nF} \ln Q$$

\]

where Q is the reaction quotient, n is number of electrons transferred, F is Faraday's constant, R is the gas constant, and T is temperature in Kelvin.

- Rearranging allows you to solve for E° based on experimental data.

3. What is the significance of the galvanic cell in electrochemistry experiments?

Answer:

A galvanic cell (voltaic cell) converts chemical energy into electrical energy spontaneously. It demonstrates how redox reactions generate a measurable voltage, allowing students to study electrode potentials and electrochemical series. The galvanic cell is significant because it provides a practical framework for understanding real-world applications like batteries, corrosion, and electroplating.

4. How do you determine the cell potential from the measured data?

Answer:

The cell potential (E_{cell}) is determined by measuring the voltage across the electrodes using a voltmeter. During the experiment:

- Connect the electrodes to the voltmeter.
- Record the voltage reading once the system stabilizes.
- Ensure the electrodes are properly immersed and connected with appropriate salt bridges or electrolytes.
- The measured voltage reflects the electromotive force (emf) of the cell under the given conditions.

For accuracy, multiple readings can be averaged, and temperature should be noted, as it influences the potential.

5. What are common sources of error in electrochemistry experiments?

Answer:

Common errors include:

- Impurities in electrodes or electrolytes.
- Inconsistent electrode surface area or cleanliness.
- Fluctuations in temperature.
- Poor electrical connections or faulty measurement devices.

- Inaccurate concentration measurements.
- Not allowing the system to reach equilibrium before recording data.

Mitigating these errors involves meticulous preparation, calibration, and controlled experimental conditions.

Key Electrochemistry Calculations and Their Answers

Electrochemistry lab questions often revolve around calculations that validate theoretical principles or quantify reaction parameters. Let's explore some typical calculations and insights on how to answer them effectively.

- Calculating Standard Cell Potential (E°)

Question: Given half-cell potentials, what is the standard cell potential?

Answer Approach:

- Identify the cathode (reduction) and anode (oxidation) half-reactions.
- Use standard reduction potentials (from tables).
- Apply:

$$E^\circ_{\text{cell}} = E^\circ_{\text{cathode}} - E^\circ_{\text{anode}}$$

- Ensure all potentials are in volts and correctly assigned.

Expert Tip: Always confirm which cell potential tables you're using and whether the values are for reduction; adjust sign if the half-reaction is written as oxidation.

- Applying the Nernst Equation to Find Cell Potential at Non-Standard Conditions

Question: How do you determine the cell potential at a specific temperature and ion concentration?

Answer Approach:

- Recall the Nernst equation:

$$E = E^\circ - \frac{RT}{nF} \ln Q$$

$$E = E^\circ - \frac{RT}{nF} \ln Q$$

$$E = E^\circ - \frac{0.0592}{n} \log Q$$

or in simplified form at 25°C:

$$E = E^\circ - \frac{0.0592}{n} \log Q$$

$$E = E^\circ - \frac{0.0592}{n} \log Q$$

$$E = E^\circ - \frac{0.0592}{n} \log Q$$

- Determine the reaction quotient (Q) based on ion concentrations.
- Plug in known values and perform calculations meticulously.
- Discuss how changes in concentration influence cell potential.

Expert Tip: Use natural logs if needed, and convert units properly. Always state assumptions about temperature and concentration units.

Answer Approach:

- Use Faraday's law:

$$m = \frac{Q \times M}{z \times F}$$

$$m = \frac{Q \times M}{z \times F}$$

$$m = \frac{Q \times M}{z \times F}$$

where:

- $Q = I \times t$ (charge in Coulombs),
- M = molar mass,
- z = number of electrons per ion in the reaction,
- F = Faraday's constant (~ 96485 C/mol).
- Convert current and time into charge.

In the reaction: $2\text{FeCl}_3 + 3\text{Sn} \rightarrow 2\text{Fe} + 3\text{SnCl}_2$, identify the species being oxidized and reduced.

Solution:

- Fe in FeCl_3 : +3
- Sn in Sn: 0 (elemental)
- Sn in SnCl_2 : +2

Oxidation: $\text{Sn (0)} \rightarrow \text{Sn (+2)}$ (oxidized)

Reduction: $\text{Fe (+3)} \rightarrow \text{Fe (0)}$ (reduced)

Tip: Remember that oxidation involves increase in oxidation state, reduction involves decrease.

Standard Electrode Potentials and Cell Voltage

Sample Question:

Given the standard reduction potentials:

$$\text{Zn}^{2+}/\text{Zn} = -0.76 \text{ V}$$

$$\text{Cu}^{2+}/\text{Cu} = +0.34 \text{ V}$$

Calculate the emf of the cell: $\text{Zn} \mid \text{Zn}^{2+} \parallel \text{Cu}^{2+} \mid \text{Cu}$.

Solution:

$$\text{Cell emf} = E^{\circ}(\text{cathode}) - E^{\circ}(\text{anode})$$

$$= +0.34 \text{ V} - (-0.76 \text{ V}) = +1.10 \text{ V}$$

Tip: Always identify cathode and anode based on standard potentials.

$$E = E^{\circ} - (0.0592 / n) \log(Q)$$

$$Q = [\text{Zn}^{2+}]/[\text{Cu}^{2+}] = 1 / 0.01 = 100$$

$$E = 1.10 \text{ V} - (0.0592 / 2) \log(100)$$

$$= 1.10 \text{ V} - 0.0296$$

$$= 1.10 \text{ V} - 0.0592$$

$$\approx 1.04 \text{ V}$$
