Understanding the concepts and solutions in engineering economy is essential for students and professionals involved in project evaluation, cost analysis, and decision-making processes. The 15th edition of Engineering Economy offers numerous problems designed to enhance practical understanding. Among these, Problem 1 often serves as an introductory exercise that lays the foundation for more complex analyses. This article provides an in-depth, step-by-step solution to Problem 1 from the 15th edition, along with explanations of relevant concepts and methodologies to ensure clarity and reinforce learning.

Overview of Engineering Economy and Its Significance

Before delving into the specific problem, it's important to grasp the broader context of engineering economy.

What is Engineering Economy?

Engineering economy involves applying economic principles to evaluate the cost-effectiveness of engineering projects and alternatives. It aids in making informed decisions by comparing the costs and benefits over the lifespan of projects or investments.

Key Concepts in Engineering Economy

- Present Worth (PW): The current value of a series of future cash flows discounted at a specific interest rate.
- Future Worth (FW): The value of cash flows at a specified future date.
- Annual Worth (AW): The uniform annual equivalent of cash flows over the project life.
- Interest Rate (i): The rate used to discount future cash flows to their present value.
- Reinvestment and Capital Recovery: Considerations involved in project evaluations.

Understanding Problem 1 from the 15th Edition

Although the specific details of Problem 1 vary by edition, the problem generally involves evaluating

projects or investments based on given cash flows, interest rates, or lifespans. To illustrate, let's consider a typical problem scenario:

Sample Problem Statement:

> "Determine the most economical alternative among three proposed projects, given their initial costs, annual operating costs, salvage values, and project lifespans. Assume an interest rate of 8% compounded annually."

The aim is to identify which project offers the best economic value using the principles of engineering economy.

Step-by-Step Solution Approach

To solve such problems efficiently, follow a systematic process:

1. Gather Data and Define Assumptions

Identify all relevant data:

- Initial cost (C_0)
- Annual operating costs (A)
- Salvage value (S)
- Lifespan (n)
- Interest rate (i)

Assumptions:

- The projects are mutually exclusive.
- Cash flows occur at the end of each year unless specified otherwise.
- The interest rate remains constant over the project durations.

2. Choose the Appropriate Method of Analysis

Depending on the data, select among:

- Present Worth Analysis: Suitable when comparing projects with different lifespans.
- Annual Worth Analysis: Useful for uniform comparison over different periods.

- Future Worth Analysis: When future values at a specific date are relevant.

3. Calculate Present Worth (PW) of Each Alternative

The general formula for present worth considering initial costs, annual costs, and salvage value is:

\[

$$PW = -C_0 - A \times P/A(i, n) + S \times P/F(i, n)$$

\]

Where:

- $P/A(i, n)$ is the Present Worth of a series of 1 per year for (n) years.
- $P/F(i, n)$ is the Present Worth of a single future sum after (n) years.

Formulas:

\[

$$P/A(i, n) = \frac{1 - (1 + i)^{-n}}{i}$$

\]

\[

$$P/F(i, n) = (1 + i)^{-n}$$

\]

4. Calculate the Present Worth for Each Project

Compute P/A and P/F using the provided data and plug into the formula.

Example Calculation:

Suppose Project A has:

- Initial cost $(C_0 = \$50,000)$
- Annual operating costs $(A = \$5,000)$
- Salvage value $(S = \$10,000)$
- Lifespan $(n = 10)$ years
- Interest rate $(i = 8\%)$

Calculate:

$\backslash$

$$P/A(0.08, 10) = \frac{1 - (1 + 0.08)^{-10}}{0.08} \approx 6.710$$

$\backslash$

$\backslash$

$$P/F(0.08, 10) = (1 + 0.08)^{-10} \approx 0.463$$

$\backslash$

Then:

$\backslash$

$$PW_A = -50,000 - 5,000 \times 6.710 + 10,000 \times 0.463$$

$\backslash$

$\backslash$

$$PW_A = -50,000 - 33,550 + 4,630 = -78,920$$

$\backslash$

Repeat for other projects.

5. Make a Comparative Analysis

Once the present worths are calculated for all alternatives, compare the values:

- The project with the least negative (or highest) present worth is considered the most economical.

6. Additional Considerations

- If projects have different lifespans, consider the Common Life Method or Replacement Analysis.
- For projects involving significant salvage values, ensure they are appropriately discounted.
- Sensitivity analysis can be performed to assess the impact of interest rate changes.

Example: Complete Solution for Multiple Projects

Let's analyze three hypothetical projects:

Project	Initial Cost (\\$)	Annual Cost (\\$)	Salvage (\\$)	Life (years)
A	50,000	5,000	10,000	10
B	60,000	4,000	12,000	12
C	55,000	4,500	9,000	9

Assuming an interest rate of 8%, calculations would proceed as outlined previously.

Interpreting Results and Making Decisions

After calculating the present worth for each project, the decision hinges on economic efficiency:

- The project with the highest present worth (least negative or most positive) is the most economical.
- If all projects have negative present worths, none may be economically justified, prompting reconsideration of alternatives.

Note: Always consider qualitative factors and strategic fit in addition to quantitative analysis.

Additional Tips for Solving Engineering Economy Problems

- Check Data Consistency: Ensure all cash flows are appropriately discounted or compounded.
- Use Tables and Software: Engineering economy tables or software like Excel can expedite calculations.
- Understand the Context: Know whether to analyze on an annual, present, or future basis based on project characteristics.
- Beware of Assumptions: Be clear about assumptions regarding interest rates, project lifespans, and cash flow timings.

Engineering Economy 15th Edition Problem 1 Solution: A Comprehensive Guide to Approach and Resolve

When tackling problems from Engineering Economy, 15th Edition, Problem 1 often serves as an introductory yet vital exercise that sets the tone for understanding fundamental economic decision-making in engineering projects. This problem typically involves analyzing costs, benefits, and economic feasibility of a proposed project or investment, requiring a clear grasp of concepts like present worth, annual worth, and rate of return. In this guide, we will break down the solution approach systematically, providing a detailed step-by-step methodology that can be applied to similar problems in the book and beyond.

Understanding the Context of Engineering Economy Problems

Before diving into calculations, it's essential to understand the core purpose of these problems: to evaluate different alternatives based on their economic merits. The goal is to identify the most cost-effective or profitable option considering factors such as initial costs, operating expenses, salvage values, and project lifespans.

Key concepts often involved include:

- Present Worth (PW): The current equivalent of a series of future cash flows.
- Annual Worth (AW): The equivalent uniform annual amount over the project's life.
- Internal Rate of Return (IRR): The discount rate that makes the net present value of cash flows zero.
- Payback Period: Time needed to recover the initial investment.

Step 1: Carefully Read the Problem and Extract Data

Begin by identifying all relevant data points provided:

- Initial investment costs
- Operating and maintenance costs
- Salvage or residual values
- Project lifetimes
- Discount or interest rate
- Any revenue or cost savings

Tip: Make a list or table of these data to clarify the inputs for your calculations.

Step 2: Determine the Appropriate Economic Analysis Method

Depending on the problem specifics, select the most suitable analysis:

- Present Worth Analysis: For comparing alternatives over a common time horizon.
- Annual Worth Analysis: When comparing projects with different lifespans or to determine equal annual costs.
- Rate of Return Calculation: To find the profitability rate of an investment.
- Payback Period: For quick assessments of investment recoverability.

Often, problems in Engineering Economy require calculating the present worth of costs or benefits and then making decisions based on comparisons.

Step 3: Calculate Present Worth (PW)

The core calculation involves bringing all cash flows to their present value using the given interest rate. For each alternative:

- Identify Cash Flows: Initial costs, annual costs/benefits, salvage values.
- Use Present Worth Formulas:

For a uniform series (like annual costs or benefits):

$$[PW = A \times P/A(i, n) + F \times P/F(i, n)]$$

Where:

- (A) = annual cash flow
- (F) = future (salvage) value
- (i) = interest rate per period
- (n) = number of periods
- $(P/A(i, n))$ = present worth factor of a uniform series
- $(P/F(i, n))$ = present worth factor of a future sum

Example formulas:

- $(P/A(i, n) = \frac{1 - (1 + i)^{-n}}{i})$
- $(P/F(i, n) = (1 + i)^{-n})$

- Sum all discounted cash flows to determine the total present worth.

Step 4: Calculate Annual Worth (if applicable)

Converting the present worth to an equivalent annual amount helps compare alternatives with different lifespans:

$$[AW = PW \times A/P(i, n)]$$

Where:

$$[A/P(i, n) = \frac{i(1 + i)^n}{(1 + i)^n - 1}]$$

This allows a straightforward comparison of options in uniform annual terms.

Step 5: Make the Decision

Compare the calculated values:

- For cost analysis, the alternative with the lowest present worth or annual cost is generally preferable.
- For investment projects, the highest net present value or internal rate of return is preferred.
- Consider qualitative factors such as risk, project feasibility, and strategic fit.

Practical Example: Hypothetical Scenario

Let's illustrate with a simplified example inspired by typical Engineering Economy problems:

Given Data:

- Alternative A:
- Initial cost: \$50,000
- Annual operating cost: \$5,000
- Salvage value after 10 years: \$10,000
- Discount rate: 8%
- Project life: 10 years

Solution Approach:

- Calculate present worth of operating costs:

$$PW_{\text{operating}} = 5,000 \times P/A(8\%, 10)$$

- Calculate present worth of salvage value:

$$PW_{\text{salvage}} = 10,000 \times P/F(8\%, 10)$$

- Total present worth:

$$PW_{\text{total}} = 50,000 + PW_{\text{operating}} - PW_{\text{salvage}}$$

- Convert to annual worth:

$$[AW = PW_{\text{total}} \times A/P(8\%, 10)]$$

- Compare with alternative options using the same process.

Additional Tips for Solving Engineering Economy Problems

- Always double-check the period units: Are cash flows annual, semi-annual, or otherwise?
- Use financial tables or calculator functions for (P/A) , (P/F) , and (A/P) factors.
- Be consistent with the interest rate and time period units.
- Document each step clearly to avoid errors and facilitate review.

Understanding Engineering Economy

What is Engineering Economy?

Engineering economy is a branch of applied economics that helps engineers and decision-makers analyze the financial aspects of engineering projects. Its primary goal is to ensure that resources are allocated efficiently, maximizing value while minimizing costs. It involves evaluating different project alternatives based on their economic merits, considering factors such as initial investment, operating costs, maintenance, salvage value, and the time value of money.

The Role of Leland T. Blank in Engineering Economy

Leland T. Blank has significantly contributed to the development and dissemination of engineering economy principles through textbooks, academic courses, and professional guidance. His work emphasizes a systematic approach to economic decision-making, combining theoretical foundations with practical tools. His methods are widely adopted in engineering curricula and industry practices worldwide, making complex financial evaluations accessible and straightforward for engineers.

Fundamental Concepts in Engineering Economy According to Leland T. Blank

Time Value of Money

One of the core principles in Blank's approach is the time value of money, which recognizes that a dollar today is worth more than a dollar in the future due to potential earning capacity. This concept underpins most economic evaluations in engineering, employing techniques such as:

- Present Worth (PW)
- Future Worth (FW)
- Annual Worth (AW)
- Rate of Return (ROR)

These methods allow engineers to compare cash flows occurring at different times by converting them into a common basis, facilitating accurate project comparisons.

Cost Analysis and Classification

Blank emphasizes the importance of detailed cost analysis, which involves categorizing costs into:

- Initial costs: Expenditures required to start a project (e.g., purchase of equipment, installation).

- Operating costs: Recurring expenses during the project's life (e.g., energy, labor).
- Maintenance costs: Upkeep expenses to keep equipment operational.
- Salvage value: Estimated residual value at the end of the project's useful life.

Proper classification enables precise cash flow modeling, a critical step in economic evaluation.

Economic Equivalence and Comparison

Blank introduces the concept of economic equivalence, allowing engineers to compare different projects or alternatives on a common financial basis. This involves calculating equivalent annual costs or benefits, ensuring fair comparisons despite differing project durations or cash flow patterns.

Key Methods and Techniques in Engineering Economy

Present Worth Analysis

Present worth analysis is the most fundamental technique, converting all future cash flows into their present value using a discount rate. The formula considers the time value of money:

$$PW = \sum \frac{F_t}{(1 + i)^t}$$

Where:

- F_t = future cash flow at time t
- i = interest rate or discount rate
- t = year or period

This method allows engineers to determine whether a project's benefits outweigh its costs, guiding investment decisions.

Future Worth and Annual Worth

- Future Worth (FW): Calculates the value of cash flows accumulated at the end of a project's life.
- Annual Worth (AW): Converts all cash flows into an equivalent annual amount, useful for comparing projects with different durations.

Rate of Return and Benefit-Cost Ratio

- Rate of Return (ROR): Finds the interest rate at which the present worth of benefits equals the present worth of costs.
- Benefit-Cost Ratio (BCR): Divides total benefits by total costs; a ratio greater than 1 indicates a profitable project.

Payback Period and Break-Even Analysis

These simpler methods estimate the time needed to recover initial investment, providing quick assessments for project viability.

Practical Applications of Engineering Economy

Capital Budgeting in Industry

Manufacturing firms utilize engineering economy principles to decide on equipment purchases, plant expansions, or new technology investments. By analyzing cash flows and applying present worth or rate of return calculations, companies can prioritize projects that offer the best financial returns.

Infrastructure and Public Works

Government agencies and municipalities apply these methods for evaluating infrastructure projects such as bridges, highways, and water treatment plants. Economic analysis ensures public funds are allocated efficiently and projects are sustainable in the long run.

Renewable Energy Projects

In the context of renewable energy, engineering economy helps assess the viability of solar farms, wind turbines, and bioenergy projects. It accounts for upfront costs, operational savings, environmental benefits, and policy incentives.

Challenges and Considerations in Engineering Economy

Uncertainty and Risk

Blank highlights that real-world projects often involve uncertainties like fluctuating costs, interest rates, or technological obsolescence. Incorporating risk analysis, sensitivity studies, and probabilistic models enhances decision robustness.

Life Cycle Costing

Evaluating all costs over a project's entire life cycle, including disposal or salvage, ensures

comprehensive economic analysis. This approach prevents short-term savings from overshadowing long-term expenses.

Inflation and Economic Changes

Adjusting analyses for inflation and changing economic conditions is essential. Blank's methods can be adapted by selecting appropriate discount rates and updating cash flow assumptions regularly.

Educational and Professional Significance

Teaching Engineering Economy

Leland T. Blank's textbooks and instructional materials serve as foundational resources in engineering curricula worldwide. They provide structured frameworks, illustrative examples, and practical exercises that prepare students for real-world decision-making.

Professional Practice

Engineers equipped with economic analysis skills can contribute more effectively to project planning, cost estimation, and strategic management. Mastery of Blank's methods enhances credibility and decision quality in engineering projects.

Conclusion

Engineering economy Leland T. Blank remains a vital discipline that empowers engineers to make informed, financially sound decisions. By integrating principles like the time value of money, cost analysis, and economic comparison methods, professionals can optimize resource allocation and ensure project success. As infrastructure demands grow and technological innovations emerge, the importance of engineering economy and the guidance provided by Leland T. Blank continues to be indispensable in shaping sustainable and economically viable engineering solutions.

cases in engineering economy solutions

Cases in engineering economy solutions play a crucial role in guiding engineers, project managers, and decision-makers toward making informed financial choices in engineering projects. These cases exemplify real-world scenarios where economic principles are applied to evaluate costs, benefits, risks, and alternatives to optimize resource allocation and maximize returns. Understanding these cases helps professionals develop a systematic approach to solving complex

financial problems, ensuring project viability and sustainability. In this comprehensive article, we will explore various cases in engineering economy solutions, illustrating methods, strategies, and best practices used to evaluate and select the most economical options across different engineering sectors.

Introduction to Engineering Economy Cases

Engineering economy involves analyzing the costs and benefits associated with engineering projects to determine the most economical solution. Cases in this field often involve evaluating various alternatives, considering factors such as initial investment, operating costs, salvage value, and the time value of money. These cases serve as practical examples for applying theoretical concepts like present worth, future worth, annual worth, and rate of return.

Common Types of Engineering Economy Cases

Understanding typical cases helps in recognizing patterns and developing a structured approach to solving similar problems.

1. Replacement Decisions

Replacement cases involve deciding whether to replace an existing asset or continue operating it. Key considerations include:

- Asset age and condition
- Operating and maintenance costs
- Salvage value
- Cost of new equipment
- Technological obsolescence

2. Equipment Selection and Investment Analysis

These cases focus on choosing the most economical equipment or investment option among multiple alternatives, considering factors like:

- Initial costs
- Operating costs
- Efficiency
- Longevity
- Residual value

3. Cost Reduction and Process Improvement

Cases here aim to identify opportunities for reducing costs or improving processes without compromising quality or safety, often through:

- Process redesign
- Material substitution
- Technological upgrades

4. Project Feasibility and Financial Analysis

Assessing whether a project is financially viable using techniques such as:

- Net Present Value (NPV)
- Internal Rate of Return (IRR)
- Benefit-Cost Ratio (BCR)

Case Study 1: Equipment Replacement Decision

Scenario

A manufacturing plant has a machine that is 8 years old. The machine's original cost was \$50,000, and it has a salvage value of \$5,000. The annual operating costs are currently \$4,000, and these costs are expected to increase by 3% annually. The machine's useful life is 15 years, and the new machine costs \$70,000 with estimated annual operating costs of \$2,500. The plant's minimum acceptable rate of return is 10%.

Solution Approach

To determine whether to replace the machine now or continue operating it, we evaluate the total costs over the remaining useful life using present worth analysis.

Step 1: Calculate the present worth of continuing operation

- Operating costs for the remaining 7 years (since 8 years have passed)
- Salvage value at the end of 7 years

Step 2: Calculate the cost of replacement

- Initial cost of new machine
- Operating costs over the next 7 years
- Salvage value of the new machine at the end of 7 years

Step 3: Compare the total present worths

Calculations:

- Operating costs escalate at 3% annually.
- Use present worth formula for escalating costs:

$$PW = \text{Annual Cost} \times \frac{1 - (1 + g)^{-n}}{i - g}$$

where:

- g = growth rate (3%)
- i = discount rate (10%)
- n = number of years

- For continuing operation:

$$PW_{\text{oper}} = 4000 \times \frac{1 - (1 + 0.03)^{-7}}{0.10 - 0.03}$$

- For the new machine:

$$PW_{\text{new}} = 70,000 + 2,500 \times \frac{1 - (1 + 0.03)^{-7}}{0.10 - 0.03} - \text{salvage value discounted}$$

Decision:

- If the present worth of keeping the old machine exceeds that of replacing it, replacement is justified.

Case Study 2: Investment Analysis for a New Project

Scenario

A company is considering investing in a new production line that costs \$200,000. The project is expected to generate additional annual net cash inflows of \$50,000 for 6 years. The company's required rate of return is 12%. The salvage value at the end of 6 years is estimated at \$20,000.

Solution Approach

Use the Net Present Value (NPV) method to evaluate the project's viability.

Step 1: Calculate Present Worth of Cash Inflows

$$PW_{\text{inflows}} = \$50,000 \times \frac{1 - (1 + 0.12)^{-6}}{0.12}$$

Step 2: Add salvage value discounted to present

$$PV_{\text{salvage}} = \$20,000 \times (1 + 0.12)^{-6}$$

Step 3: Determine NPV

$$NPV = PW_{\text{inflows}} + PV_{\text{salvage}} - \text{initial investment}$$

Decision:

- If $NPV > 0$, the investment is financially justified.
- If $NPV < 0$, the investment is not financially justified.

Case Study 3: Cost Reduction Through Process Optimization

Scenario

An industrial process incurs annual costs of \$150,000. Management considers investing in new technology that costs \$300,000 but promises to reduce annual operating costs to \$100,000. The new equipment has a lifespan of 10 years with no salvage value, and the company's discount rate is 8%.

Solution Approach

Calculate the payback period and analyze the cost savings through annual worth analysis.

Step 1: Calculate the annual savings

$$\Delta C = \$150,000 - \$100,000 = \$50,000$$

Step 2: Determine the payback period

$$\text{Payback period} = \frac{\text{Initial investment}}{\text{Annual savings}} = \frac{\$300,000}{\$50,000} = 6 \text{ years}$$

Step 3: Calculate the present worth of savings over 10 years

$$AW = \$50,000$$

$$PW_{\text{savings}} = AW \times \frac{1 - (1 + i)^{-n}}{i}$$

Plugging in the numbers:

$$PW_{\text{savings}} = \$50,000 \times \frac{1 - (1 + 0.08)^{-10}}{0.08}$$

Decision:

- If the present worth of savings exceeds the initial cost, the investment is economical.
- Otherwise, consider alternative options.

Best Practices in Analyzing Engineering Economy Cases

To effectively solve cases in engineering economy solutions, practitioners should adhere to several best practices:

1. Clearly Define Objectives and Constraints

Understanding the project's goals and limitations ensures relevant analysis and accurate decision-making.

2. Gather Accurate Data

Reliable data on costs, salvage values, inflation, and discount rates are essential for credible results.

3. Use Appropriate Economic Evaluation Methods

Select methods like NPV, IRR, payback period, or benefit-cost ratio based on the context.

4. Consider Multiple Alternatives

Always evaluate different options to identify the most economical solution.

5. Incorporate Sensitivity Analysis

Assess how changes in key assumptions impact outcomes to understand risk and robustness.

Conclusion

Cases in engineering economy solutions exemplify the practical application of financial principles to engineering decisions. From replacement analysis and investment evaluation to cost reduction strategies, these cases reinforce the importance of systematic analysis and sound judgment. By mastering various evaluation techniques and understanding real-world scenarios, engineers and decision-makers can optimize resource utilization, enhance project profitability, and ensure sustainable growth. Whether dealing with equipment replacement, project investments, or process improvements, applying the right economic tools and approaches is fundamental to achieving successful outcomes in engineering projects.

Engineering Economy Solutions: A Deep Dive into Practical Applications and Case Studies

In the world of engineering, decision-making is an integral aspect that can significantly influence project success, financial viability, and long-term sustainability. Engineering economy solutions serve as a systematic approach to evaluating the economic merits of different engineering projects, options, or investments. This article explores various cases and real-world applications of engineering economy solutions, providing insights into methodologies, decision criteria, and best practices that professionals employ to optimize outcomes.

Introduction to Engineering Economy Solutions

Engineering economy is a branch of economic analysis dedicated to comparing the costs and benefits associated with engineering projects over their life spans. The primary goal is to determine the most economical alternative that satisfies technical requirements while minimizing costs and

maximizing benefits.

Key Components of Engineering Economy Solutions:

- Cost Analysis: Identifying and quantifying all relevant costs (initial, recurring, and residual).
- Benefit Analysis: Estimating the benefits derived from the project or alternative.
- Time Value of Money: Applying concepts such as present worth, future worth, and annuities.
- Economic Metrics: Calculating net present value (NPV), internal rate of return (IRR), payback period, and benefit-cost ratio.
- Decision Making: Using comparative analysis to select the optimal alternative.

Case 1: Evaluating Alternative Power Generation Methods

Background

A utility company seeks to determine whether to invest in a new coal-fired power plant or a solar photovoltaic (PV) installation. Both options have distinct initial costs, operational expenses, environmental impacts, and lifespan. The goal is to evaluate which alternative offers the best economic value over a 20-year period.

Approach

The engineering economy solution involves:

- Estimating Initial Investment: Capital costs for both options.
- Operational and Maintenance Costs: Annual expenses over the project's lifespan.
- Salvage Value: Residual value at the end of the period.
- Discount Rate: Reflecting the company's cost of capital, assumed at 8%.

Analysis

- Initial Costs:
 - Coal Plant: \$500 million
 - Solar Plant: \$300 million

- Annual Operating Costs:

- Coal Plant: \$50 million
- Solar Plant: \$10 million

- Lifespan: 20 years

- Salvage Values:

- Coal Plant: \$50 million
- Solar Plant: \$20 million

- Methodology:

Using the present worth analysis, the total costs or benefits are discounted to their present value for comparison.

Calculations:

- Present Worth of Operating Costs (PWOC):

\[

$$PWOC = \text{Annual Cost} \times \frac{1 - (1 + i)^{-n}}{i}$$

\]

- Present Worth of Salvage Value:

\[

$$PWSV = \text{Salvage} \times (1 + i)^{-n}$$

\]

Results:

- Coal Plant:

- PWOC ? $\$50 \text{ million} \times 11.33$? $\$566.5 \text{ million}$

- PWSV ? $\$50 \text{ million} \times (1 + 0.08)^{-20}$? $\$50 \text{ million} \times 0.2145$? $\$10.7 \text{ million}$

- Total Present Worth = Initial Cost + PWOC ? PWSV ? $\$500\text{M} + \$566.5\text{M} ? \$10.7\text{M} ? \$1,055.8 \text{ million}$

- Solar Plant:

- PWOC ? $\$10 \text{ million} \times 11.33$? $\$113.3 \text{ million}$

- PWSV ? $\$20 \text{ million} \times 0.2145$? $\$4.29 \text{ million}$

- Total Present Worth = $\$300\text{M} + \$113.3\text{M} ? \$4.29\text{M} ? \409 million

Conclusion

Based on present worth analysis, the solar photovoltaic installation offers a significantly lower total present value cost, making it the more economical choice over the 20-year span. However, other factors like environmental regulations and energy reliability should also be considered.

Case 2: Life Cycle Cost Analysis of Industrial Equipment

Background

An industrial plant plans to install a new cooling system. The decision hinges not only on purchase cost but also on maintenance, energy consumption, and operational efficiency over the equipment's expected life.

Approach

Applying Life Cycle Cost (LCC) analysis, engineers evaluate:

- Initial purchase price
- Operating costs (energy, maintenance)
- Replacement costs
- Residual or salvage value

Data Summary

- Option A (Standard Cooling System):
 - Purchase Price: \$100,000
 - Annual Maintenance: \$5,000
 - Energy Consumption: 50,000 kWh/year @ \$0.10/kWh
 - Expected Life: 10 years
 - Salvage Value: \$10,000
- Option B (High-Efficiency System):
 - Purchase Price: \$150,000
 - Annual Maintenance: \$3,000
 - Energy Consumption: 30,000 kWh/year @ \$0.10/kWh
 - Expected Life: 10 years
 - Salvage Value: \$15,000

Analysis

Calculating the Present Worth of Total Cost for each option over 10 years, assuming an 8% discount rate.

Option A:

- Purchase Price: \$100,000

- Maintenance PV:

\[

$$5,000 \times \frac{1 - (1 + 0.08)^{-10}}{0.08} \approx 5,000 \times 6.71 \approx \$33,550$$

\]

- Energy Cost PV:

\[

$$50,000 \times 0.10 \times 6.71 \approx 50,000 \times 0.10 \times 6.71 \approx \$33,550$$

\]

- Salvage Value PV:

\[

$$10,000 \times (1 + 0.08)^{-10} \approx 10,000 \times 0.4632 \approx \$4,632$$

\]

- Total Present Worth Cost:

\[

$$100,000 + 33,550 + 33,550 - 4,632 \approx \$162,468$$

\]

Option B:

- Purchase Price: \$150,000

- Maintenance PV:

\[

$$3,000 \times 6.71 \approx \$20,130$$

\]

- Energy Cost PV:

\[

$$30,000 \times 0.10 \times 6.71 \approx \$20,130$$

\]

- Salvage Value PV:

\[

$$15,000 \times 0.4632 \approx \$6,948$$

\]

- Total Present Worth Cost:

\[

$$150,000 + 20,130 + 20,130 - 6,948 \approx \$183,312$$

\]

Conclusion

While the high-efficiency system has higher initial costs, the lower operating expenses lead to a marginally higher total present worth cost compared to the standard system. The final decision should also consider non-quantitative factors such as environmental impact and energy efficiency mandates.

Case 3: Cost-Benefit Analysis for Infrastructure Projects

Background

A city is evaluating whether to upgrade its public transportation infrastructure with a new light rail system or enhance existing bus services. The decision involves assessing economic viability, social benefits, and environmental impacts.

Approach

The engineering economy solution involves:

- Quantitative assessment of costs and benefits
- Assigning monetary values to intangible benefits like reduced congestion
- Calculating benefit-cost ratio (BCR)

Data Summary

- Light Rail System:
 - Capital Cost: \$2 billion
 - Operating Cost per Year: \$50 million
 - Expected Lifespan: 30 years
 - Estimated Benefits (reduced congestion, time savings): \$150 million/year
- Enhanced Bus Service:
 - Capital Cost: \$200 million
 - Operating Cost per Year: \$80 million
 - Expected Benefits: \$80 million/year

Analysis

Applying discounted cash flow analysis at 5%:

Light Rail:

- Present Worth of Benefits:

\[

$$150 \times \frac{1 - (1 + 0.05)^{-30}}{0.05} \approx 150 \times 18.4 \approx \$2.76 \text{ billion}$$

\]

- Present Worth of Costs:

\[

$$2,000 + 50 \times 18.4 \approx 2,000 + 920 \approx \$2.92 \text{ billion}$$

\]

- Benefit-Cost Ratio (BCR):

\[

$$\frac{2.76}{2.92} \approx 0.95$$

\]

Enhanced Bus Service:

- Benefits PV:

\[

$$80 \times 18.4 \approx \$1.47 \text{ billion}$$

\]

- Costs PV:

\[

$$200 + 80 \times 18.4 \approx 200 + 1,472 \approx \$1.67 \text{ billion}$$

\]

- BCR:
