2. Calculate Characteristic Impedance

The characteristic impedance (Z_0) is critical for impedance matching in RF circuits. Use standard formulas or online calculators to determine the width (W) of the microstrip line based on your substrate parameters and desired impedance (commonly 50 Ω).

- For $\epsilon_r > 1$, the approximate formula for $W/H > 1$ is:

$$W = (8 h \exp((Z0 / 60) \sqrt{\epsilon_r + 1}/2)) / (\exp(2 Z0 / 60 \sqrt{\epsilon_r + 1}/2) - 1)$$

- Alternatively, use built-in tools or scripts within Ansoft Designer for this calculation.

3. Create Microstrip Geometry

- Draw the microstrip line with the calculated width W on the substrate layer.
- Define the ground plane beneath the substrate.
- Ensure proper boundaries and ports are set for simulation.

4. Set Up Simulation Parameters

- Select the appropriate electromagnetic solver (e.g., HFSS or Momentum)
- Configure boundary conditions and excitation ports
- Specify frequency range for analysis (e.g., 1 GHz to 10 GHz)

5. Run the Simulation and Analyze Results

- Observe S-parameters, especially S11 (reflection coefficient) and S21 (insertion loss)
- Verify the characteristic impedance by analyzing the impedance profile
- Examine electric and magnetic field distributions for insights into performance

6. Optimize Design

- Adjust the microstrip width W based on simulation feedback
- Use parameter sweep tools to find optimal dimensions for minimal loss and desired impedance
- Repeat simulation until specifications are met
